Effective Programming Practices for Economists

Data management with pandas

Selecting rows and columns

Janoś Gabler and Hans-Martin von Gaudecker

Overview

- Selecting columns
- Selecting individual rows
- Selecting rows and columns
- Selecting rows using Boolean Series
- Selecting rows with queries

Selecting columns

```
>>> df["country"]
      Cuba
      Cuba
     Spain
     Spain
Name: country, dtype: string
>>> df[["country", "continent"]]
                           continent
  country
  Cuba
                           Americas
  Cuba
                           Americas
  Spain
                           Europe
  Spain
                           Europe
```

- Column selection is with square brackets
- For multiple columns you need double brackets:
 - Outer: selecting columns
 - Inner: defining a list of variables

Selecting individual rows

	continent	life_exp
year		
2002	Americas	77.16
2007	Americas	78.27

```
>>> df.loc[("Cuba", 2002)]

continent Americas
life_exp    77.158
Name: (Cuba, 2002), dtype: object
```

- Selection of rows needs .loc[]
- Selection is label based!
- For a MultiIndex you can specify some or all levels

Selecting rows and columns

```
>>> df.loc[1, "country"]
'Cuba'

>>> df.loc[[1, 3], ["country", "year"]]

country
year

Cuba
2007

Spain
2007
```

- Use .loc[rows, columns] to select rows and columns
- Can use everything you have seen before

Selecting rows using Boolean Series

```
df["year"] >= 2005
      False
      True
      False
       True
 Name: year, dtype: bool
 >>> df[df["year"] >= 2005]
                 continent
                                             life exp
  country
                                    year
  Cuba
                 Americas
                                    2007
                                             78.27
3 Spain
                                             80.94
                 Europe
                                    2007
```

- Comparisons of Series produce Boolean Series!
- Complex conditions with | and &
- Boolean Series can be used for selecting rows
- Works also inside .loc

Selecting rows with queries

>>> df.query("year >= 2005")						
country	continent	year	life_exp			
1 Cuba	Americas	2007	78.27			
3 Spain	Europe	2007	80.94			

>>> df.query	("year >= 200	95 & continent	== 'Europe'")
country	continent	year	life_exp
3 Snain	Furone	2007	80 94

- query selects rows based on strings with conditions
- Can use index names just as column names
- Use single quotes (') for string value inside
 the query
- More readable than selection via Boolean Series
