Effective Programming Practices for Economists

Basic Python

If conditions

Janoś Gabler and Hans-Martin von Gaudecker

Contents

- if, elif, and else
- More on Booleans
- More complex conditions
- Filtering loops

Motivation

- So far, all of our instructions in Python were very explicit
- There was no way of reacting to different situations:
 - Collecting elements of a list that fulfil a condition
 - Doing different things for different types of variables
 - **-** ...
- This is what if conditions are for

Example: clipping a number

```
>>> number = -3.1
>>> if number < -3:
   clipped = -3.0
... elif number > 3:
   clipped = 3.0
... else:
   clipped = number
>>> clipped
-3.0
```

- if , elif , and else are special keywords
- End each condition with a ::
- What happens if that condition is True needs to be indented by 4 spaces and can span one or multiple lines
- Code following False conditions is skipped
- elif x: is the same as
 else: + nested if x:

More on Booleans

```
>>> bool(0)
False
>>> bool(-1)
True
>>> bool(1)
True
>>> bool([])
False
>>> bool([1, 2, 3])
True
>>> bool("")
```

- What is not a Boolean can be converted to a Boolean
- This conversion happens implicitly after if and elif
- Can be useful and elegant but might compromise readability
- Rules of thumb:
 - 0 is False -ish
 - Other numbers are True -ish
 - Len-0 collections are False -ish
 - Len>0 collections are True -ish

More complex conditions

- Remember operators from "Assignments and Scalar Types":
 - and
 - or (inclusive)
 - not

Example:

```
if a > b and b > some_cutoff:
    do_something()
else:
    do_something_else()
```

Filtering loops

```
>>> names = ["Guy", "Ray", "Tim"]
>>> names_with_i = []
>>> for n in names:
>>> if "i" in n:
>>> names_with_i.append(n)
>>> names_with_i
['Tim']
```

- Can filter lists based on properties of items
- Can filter dictionaries based on properties of keys and/or values
- Example usecases:
 - Find elements above a cutoff
 - Extract female names
 - Exclude invalid data
