Effective Programming Practices for Economists

Data management with pandas

Selecting rows and columns

Janoś Gabler and Hans-Martin von Gaudecker

Overview

- Selecting columns
- Selecting individual rows
- Selecting rows and columns
- Selecting rows using Boolean Series
- Selecting rows with queries

Selecting columns

```
>>> df["country"]

0    Cuba
1    Cuba
2    Spain
3    Spain
Name: country, dtype: string

>>> df[["country", "continent"]]
```

	country	continent
0	Cuba	Americas
1	Cuba	Americas
2	Spain	Europe
3	Spain	Europe

- Column selection is with square brackets
- For multiple columns you need double brackets:
 - Outer: selecting columns
 - Inner: defining a list of variables

Selecting individual rows

```
continentlife_expyear2002Americas77.162007Americas78.27
```

```
>>> df.loc[("Cuba", 2002)]

continent Americas
life_exp 77.158
Name: (Cuba, 2002), dtype: object
```

- Selection of rows needs .loc[]
- Selection is label based!
- For a MultiIndex you can specify some or all levels

Selecting rows and columns

```
>>> df.loc[1, "country"]
'Cuba'

>>> df.loc[[1, 3], ["country", "year"]]

country year

Cuba 2007

Spain 2007
```

- Use .loc[rows, columns] to select rows and columns
- Can use everything you have seen before

Selecting rows using Boolean Series

```
df["year"] >= 2005
0
     False
      True
     False
      True
Name: year, dtype: bool
>>> df[df["year"] >= 2005]
country
             continent
                            year
                                     life exp
Cuba
             Americas
                            2007
                                     78.27
                                     80.94
Spain
             Europe
                            2007
```

- Comparisons of Series produce Boolean Series!
- Complex conditions with | and &
- Boolean Series can be used for selecting rows
- Works also inside .loc

Selecting rows with queries

>>> df.query("year >= 2005")									
	country	continent	year	life_exp					
1	Cuba	Americas	2007	78.27					
3	Spain	Europe	2007	80.94					

>	>>> df.query("	year >	>=	2005	&	continent	==	'Europe'")
country		continent		year	life_exp			
3	Spain	Europe				2007	80	.94

- query selects rows based on strings with conditions
- Can use index names just as column names
- Use single quotes (') for string value inside the query
- More readable than selection via Boolean Series
